To answer this question, we first find the genus of each $M_n$. Let $P_n$ be the topological genus of the surface $M_n$, and let $B_n$ be the number of holes on one face of $M_n$ (one face in terms of the six original faces of $M_0$). Clearly $P_0 = 0$, $P_1 = 5$, and $B_n = \sum_{k=0}^{n-1} 8^k = \frac{8^n-1}{7}$. We will show that $P_n = 20P_{n-1} - 24B_{n-1} + 5 = \frac{3}{19}20^n + \frac{2}{7}8^n - \frac{59}{133}$.

$M_n$ can be constructed by arranging 20 copies of $M_{n-1}$. Note that there are 24 places where the face of an $M_{n-1}$ meets another face of an $M_{n-1}$. Counting holes as 20 copies of $M_{n-1}$ double-counts the holes on such faces, giving $24B_{n-1}$ double-counted holes. When the 20 $M_{n-1}$’s assemble, they take the same shape as $M_1$, generating $P_1 = 5$ additional holes between them, giving $P_n = 20P_{n-1} - 24B_{n-1} + 5$. To eliminate the recursion here, we use generating functions and obtain $P_n = \frac{3}{19}20^n + \frac{2}{7}8^n - \frac{59}{133}$.

A result of G. Ringels and J. W. T. Young [*“Solution of the Heawood Map-Coloring Problem.”* Proc. Nat. Acad. Sci. USA 60, 438-445, 1968.]* tells us the chromatic number of a surface of genus $p > 0$ is Heawood’s number $H = \left\lceil \frac{7 + \sqrt{1 + 48(\frac{3}{19}20^n + \frac{2}{7}8^n - \frac{59}{133})}}{2} \right\rceil$. Thus the chromatic number for any $M_n$ is

$$H_n = \left\lceil \frac{7 + \sqrt{1 + 48(\frac{3}{19}20^n + \frac{2}{7}8^n - \frac{59}{133})}}{2} \right\rceil.$$ 

The first few values of $H_n$ are 4, 11, 34, 133, and 566. It is interesting (although not entirely surprising) that $H_n$ grows exponentially ($H_{100} > 10^{65}$).
